# What is Emscripten?

Emscripten is a compiler, toolchain, and runtime library for running C and C++ code in web browsers (or Node.js), without plugins.

*(This talk will focus mainly on code run within a web browser.)*

# What is Emscripten?

- it is a C/C++ compiler and toolchain
  - Clang-backed by default
  - also accepts LLVM byte code as input
- Outputs:
  - JavaScript
  - WebAssembly (a newer, smaller format)
- it offers a runtime, with C and C++ APIs to help work with web browsers (or NodeJS)
- has many limitations over popular, ‘native’, C/C++ platforms, however many things are possible (and demonstratable)

# Demo Time

Qt

[http://example.qt.io/qt-webassembly/Slate/  
slate.html](http://example.qt.io/qt-webassembly/Slate/slate.html)

# Usable Libraries + APIs

(among others)

- stdio (`printf`, `fopen`, ...), iostreams (`std::cout`, `std::fstream`, ...)
- POSIX-style file system APIs (`opendir`, `readdir`, `stat`, ...)
  - no `std::filesystem`, yet
- graphics: OpenGL ES 2+, HTML DOM, LibSDL, ...
- audio: OpenAL, LibSDL, ...
- input (via events): keyboards, mice, touch-screen, game controllers
- partial support for sockets (via WebSockets)

# Installation

- instructions at [https://emscripten.org/docs/getting\\_started](https://emscripten.org/docs/getting_started)
- Option 1: Emscripten SDK (aka, “emsdk”)
  - capable of installing and updating many, but not all, dependency technologies
  - works on Windows, Linux, and macOS (at least)
- Option 2: via a 3rd-party package manager
  - HomeBrew (aka. “brew”), for macOS: <https://brew.sh>
  - apt-get, for Ubuntu, Debian (at least)

# Basic Usage

## “emcc” and “em++”

- similar to other, popular compiler commands
  - (i.e. gcc/g++, clang/clang++, ...)
- Examples:
  - **em++ A.cpp -o A.html**
  - **em++ B.cpp C.cpp -o BC.js**
  - **em++ D.cpp -o D.o**  
**em++ E.cpp -o E.o**  
**em++ D.o E.o -o DE.js**
  - **em++ F.cpp -o F.html -s USE SDL=2**

# Example #1

## Hello World, printf edition

```
// Compile with: em++ hello_world.cpp -o hello_world.html
```

```
#include <stdio.h>

int main() {
    const char * greeting = "Hello World";
    printf("%s\n", greeting);
}
```

# Example #2

## Hello 42, inline JavaScript

```
// Compile with: em++ hello_42.cpp -o hello_42.html
```

```
#include <emscripten.h>

int main() {
    int x = 42;
    EM_ASM({
        var greeting = 'Hello ' + $0;
        alert(greeting);
    }, x);
}
```

# Talking to Web APIs

- \*ALL\* interaction with system is done through Web APIs (DOM, WebGL, etc.)
- inline JavaScript
  - very low-level data-interop is present
- higher level libraries
  - Ebind – C++11 wrappers
    - wrap JavaScript values as C++ objects
    - wrap C/C++ structs and classes in JavaScript objects
    - call JavaScript functions with C++-style syntax

# Example #3

## Hello DOM (Document Object Model), via Embind

```
// Compile with: em++ --bind hello_dom.cpp -o hello_dom.js  
// Uses a pre-made html file (i.e. "hello_dom.html"), containing the following:  
// <div id="my_element"></div>
```

```
#include <emscripten/val.h>  
using namespace emscripten;  
int main() {  
    val my_element = val::global("document").call<val>(  
        "getElementById", val("my_element")  
    );  
    my_element.set("innerHTML", "Hello DOM!");  
}
```

# Demo Time

live-video processing (with CCV)

<https://fta2012.github.io/ccv-js/>

# Callbacks

- browsers default to running code in a cooperatively-multitasked, single-threaded environment
  - i.e. ‘while (true) {}’ can lead to the web browser hanging
  - functions may only get a few seconds before the browser takes action
  - this applies to ‘int main() { ... }’
- spawning new threads possible, but often not while sharing memory across threads
- long running programs might need to be broken up into short-running time-slices that run on:
  - periodic time-intervals
  - various notable events (user-input entered, data received, etc.)

# Example #4

## Long Running Execution

```
#include <emscripten.h>
#include <emscripten/val.h>
#include <string>
using namespace emscripten;

int update_count = 0;
void update() {
    val my_element = val::global("document").call<val>(
        "getElementById", val("my_element")
    );
    my_element.set("innerHTML", std::to_string(++update_count));
}

int main() {
    emscripten_set_main_loop(update, 0, 1);
    // code here will not run (due to last parameter to emscripten_set_main_loop)
}
```

// Compile with: em++ --bind long\_run.cpp -o long\_run.js

// Assumes presence of pre-existing html file,

// "long\_run.html", which contains:

// <div id="my\_element"></div>

# Caveats

- thread support often unavailable
  - callbacks may need to be utilized here
  - async IO options are available (on the bright side)
- limited socket support
  - via WebSockets, which are not the same as raw sockets
  - step-debugging not fully featured
    - partially-possible (in a web browser, via ‘source maps’)
    - reading/watching variables still in development (CyberDWARF)

# Caveats

- limited library support
  - often due to other caveats (such as threading restrictions)
- keyboard shortcuts may be overridden by web-browser(s)
- setjmp/longjmp not possible, nor any low-level stack manipulations
- slower than native code

# Demo Time

in-browser gaming (via Doom 3)

<http://wasm.continuation-labs.com/d3demo/>

# The End
